Preface

The purpose of this study was to develop an analytical framework for assessing future force structure requirements under uncertainty. With the end of the Cold War, the U.S. has entered into a new era of defense planning marked by declining defense budgets and uncertainty about the future. The analytical models used during the Cold War to address future force structure questions now seem inadequate for dealing with the uncertainty inherent in today's questions. The framework developed during this research provides one approach to answering these questions.

While the framework presented in this thesis has not yet stood the test of time, it has already provided some useful force-structuring insights, particularly about the need to maintain a healthy defense-industrial base. The framework was designed with flexibility in mind. With this flexibility, there is plenty of room for additional experimentation with the framework as it now stands and for future improvement.

I would like to thank my faculty advisor, Col Greg Parnell, and reader, Lt Col Jack Jackson, for their help during this effort. I am particularly grateful for their patience during some difficult times. I would also like to thank my family and friends for their constant love and support.

Abstract

The objective of this research was to develop an analytical framework to assess future force structure requirements under the major uncertainties inherent in the post-Cold War era. Among the uncertainties are the frequency and nature of future threats to U.S. interests and the cost of maintaining, building, and demobilizing forces. The centerpiece of the methodology is a computer model which simulates the development of threats to U.S. interests and the actions the U.S. takes to protect those interests. From this simulation, the costs and risks associated with different policy alternatives can be estimated. The simulation is set within a broader decision-analysis framework which provides the philosophy for determining the inputs to the simulation and for analyzing the output from the simulation. The research included an analysis of 24 policy alternatives involving the size of the Base Force, the "safety margin" maintained between the force size and the force requirement, the rate of force buildup, and the rate of force demobilization. The results suggest that the buildup rate is a key factor in lowering the costs of the U.S. military while controlling the risk of being unable to protect U.S. interests.

AN ANALYTICAL FRAMEWORK FOR ASSESSING FUTURE FORCE STRUCTURE REQUIREMENTS UNDER UNCERTAINTY

I. Introduction

Background.

With the end of the Cold War, the defense strategy of the United States has changed from a focus on the Soviet Union to a focus on regional conflict around the globe. The U.S. no longer faces a well-defined enemy as it did during the Cold War, but threats to U.S. interests still remain. According to The National Security Strategy of the United States: January 1993,

While we no longer face the single defining threat which dominated our policy, budgets, force structures, and indeed our fears for forty years, multiple threats to our security still remain. Today's challenges are more complex, ambiguous and diffuse than ever before. They are political, economic, and military; unilateral and multilateral; short- and long-term. (White House, 1993:1)

The document further states that,

Even as the danger of global war recedes, the potential for smaller but still highly destructive conflicts between nations and within nations is growing. We simply do not and cannot know all the challenges that will arise in the future. What we do know is that our citizens and our interests will be challenged again. We must remain strong enough to protect and defend them. (White House, 1993: ii)

The enemy the U.S. will face in the future is of unknown size and capability in an unknown location and at an unknown time. Yet, questions about the structure of the military forces with which the U.S. will meet this enemy must be answered today. During the Cold War, a myriad of analytical models were developed to help mold the size,

composition, and employment strategies of U.S. military forces. Unfortunately, despite their success during the Cold War, these models now seem inadequate for the uncertainties inherent in today's difficult force structuring decisions. What is needed is a fresh approach to address the problem of structuring military forces for the future, because there is one thing that is clear, "... if we are to learn anything from the often tragic history of this century, it is first that the future is uncertain, ..." (White House, 1993: i).

Problem Statement.

U.S. military planners do not have an adequate analytical framework for assessing future force structure requirements under the major uncertainties inherent in today's world environment.

Research Objective.

The objective of this research is to develop an analytical framework to assess future force structure requirements under the major uncertainties of today's world environment.

Research Questions.

The prevailing paradigm for structuring military forces today is to maintain a "Base Force" capable of meeting the vast majority of future threats and then to reconstitute force structure when deemed necessary for larger threats. In view of this paradigm,

- What size should the "Base Force" be to adequately protect U.S. interests while controlling costs?
- As threats develop and force requirements change, what force-size "safety margin" should be maintained to minimize the risk of being unprepared?
- If force reconstitution is necessary, how quickly should forces be built up?

• As threats are reduced, how quickly should forces be returned to their "Base Force" size (i.e., demobilized)?

Scope.

- The analytical framework will not attempt to define the composition of future forces (e.g., the types and numbers of fighter aircraft).
- The framework will address conventional forces only. It is assumed that a sufficient strategic nuclear force is maintained to deter nuclear aggression by other nations.

Summary.

The determination of future force structure requirements is perhaps more difficult now than ever. The end of the Cold War has marked the end of a single, well-defined threat to national interests and inaugurated a period of great uncertainty about how the U.S. should prepare for future threats. Analytical models used during the Cold War to address future force structure questions seem inadequate for the ambiguity inherent in today's questions. The framework developed during this research provides one approach to answering these questions.

II. Literature Review

The literature review which follows provides background material important for understanding the methodology presented in Chapter 3. The literature review is divided into two sections: Problem-Solving Approaches and Future Force Structure Paradigms.

Problem-Solving Approaches.

This section presents an overview of two approaches commonly used to "solve" problems under uncertainty, Decision Analysis and Simulation. The overview includes the concepts and techniques underlying each approach, as well as the strengths and limitations of each approach.

<u>Decision Analysis</u>. Decision-making is the process of choosing from among alternative courses of action. As the number of alternatives grows and as the consequences become more important and/or more uncertain, the decision becomes increasingly difficult. Decision Analysis helps structure these decision problems so that the decision maker can think more systematically about the problem, taking better account of all the alternatives and uncertainties.

The basic decision analysis has four steps.

- 1. The decision maker identifies the possible courses of action.
- 2. The decision maker identifies the uncertain events, or "states of nature," relevant to the decision problem and assigns a probability-of-occurrence to each event. The consequence of any course of action is dependent not only on the course of action but also on the event which actually occurs.
- 3. The decision maker determines the consequence of each action/event pairing.

4. The decision problem is modeled (in an influence diagram or decision tree, for example) and solved. The problem solution depends on the expected consequence of each course of action and on the decision maker's risk preferences.

Strengths. The strengths of Decision Analysis include the following:

- The decision maker plays an active role in the decision analysis process. Indeed, the decision maker is central to the process. It is the decision maker's beliefs and values upon which the analysis is built.
- Decision Analysis addresses the uncertainties impinging on the problem in a very systematic way

<u>Weaknesses</u>. Decision Analysis cannot adequately address large problems where there are complex interactions between events over time.

Simulation. As explained by Ravindran,

Simulation is a numerical technique for conducting experiments on a digital computer, which involves logical and mathematical relationships that interact to describe the behavior and structure of a complex real-world system over extended periods of time. (Ravindran, 1987: 375)

Simulation is often an effective approach to studying a system which cannot be represented mathematically because of the stochastic nature of the problem, the complexity of problem formulation, or the interactions needed to adequately describe the problem under study.

Strengths. Naylor suggests that simulation analysis has the following strengths:

- 1. Through simulation, one can study the effects of certain information, organizational, and environmental changes on the operations of a system by making alterations in the model of the system and by observing the effects of these alterations on the system's behavior.
- 2. Simulation of complex systems can yield valuable insight into which variables are more important than the others in the system and how these variables interact.

- 3. Simulation can be used to experiment with new situations about which we have little or no information, so as to prepare for what may happen.
- 4. Simulation can serve as a "preservice test" to try out new policies and decision rules for operating a system, before running the risk of experimenting on the real system.
- 5. For certain type of stochastic problems the sequence of events may be of particular importance. Information about expected values and moments may not be sufficient to describe the process. (Naylor, 1971)

Weaknesses.

- Simulation cannot provide an optimal solution.
- The variability or dispersion of simulation results can be a significant problem and may require long and complex simulation analysis to draw meaningful conclusions (Ravindran, 1987: 377).

Defense Planning Paradigms.

The discussion that follows provides a brief synopsis of the evolution of force planning models over the last few years. The discussion is presented as background to the justification of the model developed in Chapter 3.

The Cold-War Paradigm. The approach the U.S. took to force-planning during the Cold War was based on five principles:

- Overall force structure was based and justified in terms of the most stressing identifiable threat scenarios.
- The analytic "requirements" for total force structure were derived for important, credible, defensively oriented, high-minded, and affordable military objectivesnotably, deterring aggression against our allies and other pivotal nations.
- Since the nuclear deterrent was the paramount instrument for avoiding general war with the Soviet Union, certain cost-cutting risks were accepted in defining the "requirements" for conventional ground and air forces.

- Having sized overall structure largely in terms of the most stressing threat, the original idea was then to "fill in" by acquiring specialized capabilities that might be needed for other scenarios, and to establish a strategic reserve suitable for varied contingencies worldwide along with adequate strategic mobility forces.
- Given a defense program consistent with the overall force structure justified in this way, the Secretary of Defense then charges the military services, the Joint Chiefs of Staff, and the various CINCs with preparing operationally not only for the principal threat scenarios but also for a wide range of smaller contingencies. (Davis: 1994: 17)

The Aspin Paradigm. In January 1992, Les Aspin, then Chairman of the House Armed Services Committee, opened up the debate on post-Cold War force structuring when he proposed a threat-based model for force planning. Aspin's model was a modified version of the Cold War paradigm, where he replaced the old Cold War threats with new ones. Aspin uses "Iraq equivalents" to specify possible threats and "Desert Storm equivalents" to specify U.S. force requirements (Winnefeld, 1992: 1). Aspin's model gives little emphasis to the uncertainty of the future, using the recent past as an indication of things to come.

The Cheney Paradigm. Shortly after Chairman Aspin proposed his threat-based model for force planning, Dick Cheney, then Secretary of Defense, presented a capabilities-based model based on the fact that we cannot predict the future with certainty. He argued that "the future environment is defined more by the unknown and the uncertain than by specific threats (Winnefeld, 1992: 1)." Cheney's model suggests a force structure capable of confronting as-yet unclear threats, and seeks to maintain a force prepared to confront any threat.

<u>Current Strategic Policy</u>. Out of the debate over post-Cold War force structuring has come the concept of maintaining a Base Force capable of meeting most threats to U.S.

interests, while guarding the capability to add force when necessary. Additionally, the U.S. had adopted the following strategic policy, as presented in <u>The National Security</u> Strategy of the United States, January 1993. (White House, 1993: 14)

The fundamental elements for our national defense strategy are:

- Strategic Deterrence and Defense. Deterring nuclear attack remains our top priority...
- Forward Presence. While reducing our forward-deployed forces, we are redefining our presence abroad with combined exercises, new access and storage agreements, security and humanitarian assistance, port visits, military-to-military contacts, and periodic and rotational deployments.
- Crisis Response. We must maintain an adequate capability to project power in
 response to crises should our efforts to deter conflict fail. The precise nature of
 our response to a crisis will, of course, depend on the interests at stake, our
 commitments to the nations involved, the level and sophistication of the threat, and
 on the capabilities of U.S. and allied forces.
- Reconstitution. As we reduce the size of our military forces in response to the demise of the global threat, we must ensure that we continue to deter potential adversaries from militarizing and, if deterrence fails, retain the capability to recreate a global warfighting capability. This "reconstitution" capability involves forming, training, and fielding new fighting units from cadres; mobilizing previously trained or new manpower; and activating the industrial base on a large scale.

III. Methodology

The previous chapter gave a brief description of Decision Analysis and Simulation.

The methodology described in this chapter incorporates principles of both approaches, allowing strengths of both approaches to be exploited.

The centerpiece of the methodology is a model which simulates the development of threats to U.S. interests and the actions the U.S. takes to protect those interests. The consequences of the actions, in the form of costs and risks, are dependent on the actions themselves and on the "state of the world" at the time of action.

The simulation model is set within a broader decision-analysis framework. While the simulation model is the "workhorse" of the methodology, the decision-analysis framework provides the "philosophical" basis for the methodology. The relationship between the decision-analysis framework and the simulation model will become clear in the sections which follow.

Definitions.

Before the methodology is presented in detail, it will be helpful to understand the following terms:

- National Interest: <u>National Security Strategy of the United States</u> delineates current
 U.S. national interests (White House, 1993:3). The U.S. protects its national interests
 through political, economic, and military means. In this analysis, we limit our attention
 to interests the U.S. chooses to protect through military action.
- Value of National Interest: Every U.S. interest has some intrinsic value. In the methodology presented here, the value of a national interest is rated on a utility scale, where "0" represents an interest with no value and "10" represents an interest with the highest value.

- Threat: A threat consists of any danger to or risk of losing a national interest.

 Threats may come from individuals, nations, coalitions, natural disasters, famine, etc.

 Again, the model only considers those threats against which military forces are employed.
- Threat Level: This is the actual amount of U.S. military force required to oppose the threat and protect the interest.
- Military Action: "Military action" is used to refer to the action taken to protect the interest threatened. The action may be warfare, deterrence, peacekeeping, environment-shaping, humanitarian relief, etc. The model differentiates between warfare and non-combat actions (deterrence, peacekeeping, humanitarian relief, etc.) but does not attempt to differentiate between types of non-combat actions. The primary difference between warfare and non-combat actions is that force attrition occurs during warfare.
- Total Force Requirement: This is the level of military force that the U.S. determines it needs at any given time. Since there may be more than one threat at any time, the Total Force Requirement is a function of the level of each threat. Additionally, the total force requirement may have a "safety margin" built into it, implying that the total force requirement will exceed the level of force actually required for military action.
- Buildup Level: This is a percentage used in the calculation of the Total Force Requirement. It is used primarily to provide a force "safety margin."
- Total Force Level: This defines the actual amount of U.S. military force at any given time.
- Base Force: This is the initial U.S. force level and the minimum force level used in the model.
- Early Warning Indicators (EWI): EWI are any signs the U.S. receives which suggest that an interest will be threatened.
- EWI Time: This is the time at which the U.S. has gathered enough EWI to decide to oppose the threat by committing military forces. In practice, the U.S. may have become aware of the threat at an earlier date and may already be using non-military means to mitigate the threat. As used in this model, however, "EWI Time" specifically identifies the time when the U.S. decides that military forces are required, estimates the threat level, and begins action to reconstitute military forces if necessary.

- Time from EWI to Start: This is the period of time the U.S. has to prepare for an impending commitment of military forces. The key to preparation is the reconstitution or buildup of military force if the current total force level is less than the estimated force requirement.
- Start Time of Military Action: This is the time that military forces are actually committed to oppose the threat and the military action commences. If the event is warfare, attrition of forces begins.
- Duration of Military Action: This is the length of time required to protect the interest (i.e., prevail against the threat) if the U.S. is able to commit enough forces to equal the threat level.
- Major Regional Conflict: The Major Regional Conflict (MRC) is the primary force building-block used in the methodology. If Desert Storm is used as the measure of the force required for an MRC, then an MRC-sized force consists of 4-5 Army divisions, 4-5 Marine Expeditionary Brigades (MEBs), 10 Air Force tactical fighter wings (TFWs), 100 Air Force heavy bombers, 4-5 Navy carrier battle groups (CVBGs), and special operations forces (SOF) (Davis, 1994: 32).
- Lesser Regional Conflict: The Lesser Regional Conflict (LRC) involves two Army light divisions, one MEB, 1-2 CVBGs, 1-2 TFWs, and SOF.
- World War: In the methodology presented, a World War (WW) is equal, in size, to 4-6 MRCs.
- Cold War: For the methodology presented, a Cold War (CW) is equal, in size, to 2-3 MRCs. However, only a portion of forces are actually committed to military action (deterrence).
- Policy Alternative: If there is more than a single decision to be made in an analysis, then a policy alternative is comprised of one possible decision choice from each decision.
- Lose Threshold: If the amount of force committed to a threat drops below the "Lose Threshold," the U.S. will lose the interest at stake.

The Decision-Analysis Framework.

The decision-analysis framework is built upon three fundamentals of decision analysis.

First, the decision maker (DM) must choose from a number of different policy alternatives.

In the future force structure problem, the decision maker must make decisions about the size of the military's base force, the level to which forces are built up in response to increased force requirements, the rate at which forces are built up, and the rate at which forces are demobilized when the force requirements are reduced.

Second, the consequence of any policy choice is dependent on the choice made and the outcome of uncertain events or "states of nature." The uncertainties relevant to the future force structure problem include:

- Frequency of threats.
- Size and nature of threats.
- Value of interests at stake.
- Accuracy of intelligence estimates.
- Time from EWI to military action.
- Types of military action.
- Duration of military actions.
- Force attrition rates.
- Cost to maintain force levels.
- Cost to reconstitute force.
- Cost to demobilize force.

 Size of force required to "hold off" a threat until sufficient forces are available to win.

Third, the decision maker makes judgements about the uncertain events and values impacting the choice of alternatives which must be considered in the analysis. In the future force structure problem the decision maker must be able to make tradeoffs between the costs of military forces, the value of interests lost when forces are unavailable, and the risks of having insufficient forces.

Where Decision Analysis falls short, vis-à-vis the future force structure problem, is in problem solution. The problem is so large and the interactions between events over time so complex that an appeal to influence diagrams and decision trees for problem solution is impractical. For this reason, computer simulation is used to model the problem and estimate the costs and risks associated with each alternative, and Decision-Analysis is used to synthesize these results into a form understandable to the decision maker.

Figure 3-1 depicts the Decision Analysis framework for the force structure problem.

Notice that the left-hand side of the framework (the decisions) and the right-hand side of the framework (the consequences) are similar to the respective sides of an influence diagram. The uncertainties are modeled in the simulation.

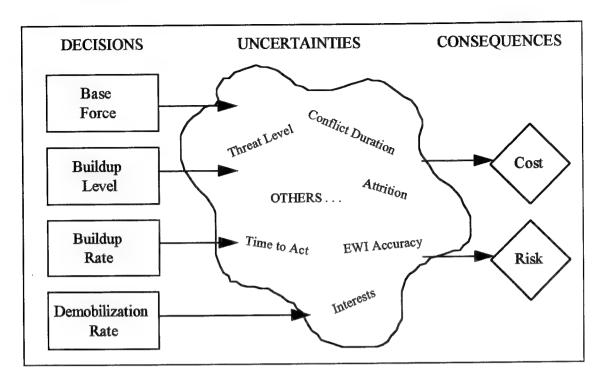

Figure 3-1. Decision Analysis Framework

The Simulation - In General.

The simulation models the occurrence of threats to U.S. interests and the actions the U.S. takes in response. The flowchart in Figure 3-2 gives a representation of how this interaction might take place in the "real world." The simulation is designed to incorporate aspects of the force structure paradigms presented in Chapter 2. For example, it appears that the U.S. is becoming more involved in "environment-shaping." "Environment-shaping" might include peacekeeping efforts or humanitarian relief to provide stability in a trouble region or to encourage goodwill towards the U.S. Since the action, at least at the outset, is a non-combat use of the military, the simulation allows the user to generate "peaceful threats" where an interest is still at stake (stability or goodwill), but protection of the interest does not require warfare.

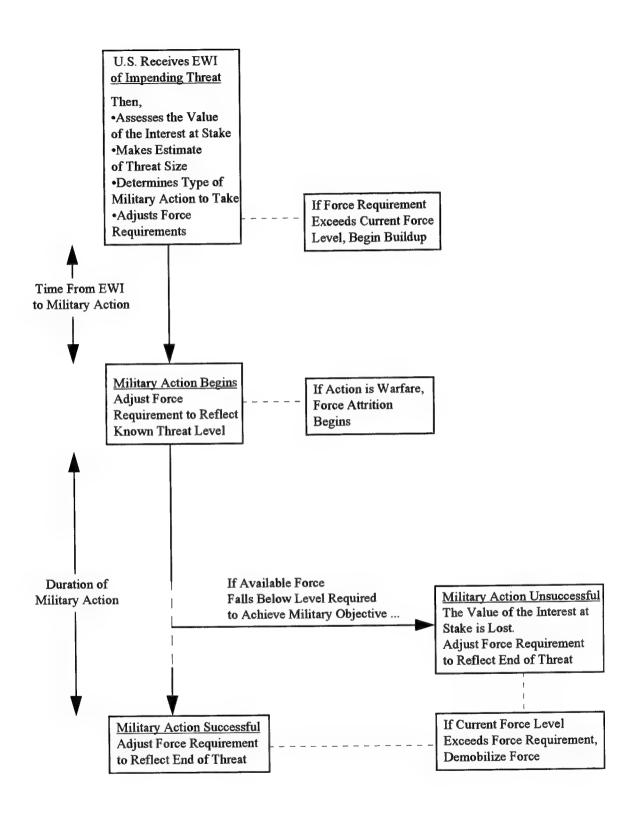

Figure 3-2. Flowchart of "Real-World" Problem

The Simulation - In Detail.

The simulation code is written in the SLAM II programming language and is broken into two parts. The first part is the network code which controls the flow and logic of the simulation. The second part contains the control statements which, among other things, determine the value of input variables and specify the number of runs to make. For a complete description of the SLAM II language, refer to Pritsker (Pritsker, 1986).

The following discussion explains how the simulation network code is constructed to imitate the model of the real world previously described. It also specifies when the user may use the control statements to define input parameters. In this way, the user may tailor the model according to his or her judgements about the real world.

Threat Generation. Because the number and timing of real-world threats is unknown, the simulation randomly generates threats according to probabilistic distributions whose parameters are defined by the user. To approximate the variability in the nature and frequency of real-world threats, the simulation is designed to create five different types of threat. These threat types represent MRCs/LRCs, WW, and CW, as summarized in Table 3-1 below. Along with their numeric and symbolic designators, the table lists the primary differentiating characteristic of each threat type.

Table 3-1
Threat Types

Threat Type	Threat Type	D' Claradairtic
Numeric Designator	Symbolic Designator	Primary Characteristics
1, 2, 3	MRC	Major or Lesser Regional Conflicts
		Small to medium threat levels.
		Interests of low to medium value.
		Military action may involve warfare,
		deterrence, or environment-shaping.
4	WW	World War
		Largest threat level.
		Interest of highest value.
		Military action involves warfare.
5	CW	Cold War
		Large threat level.
		Interest of highest value.
		Military action involves deterrence.
		*The actual force committed to military
		action is only a fraction of the threat level.

^{*} The assumption is that, during Cold War, the U.S. will build up its military forces to a relatively high level. However, only a portion of those forces are placed in an active deterrent posture (e.g., forward-deployed to guard borders). The remainder of the forces may be used to protect against MRC-type threats.

MRC threats are generated with exponentially distributed interarrival times. Because their interarrival times are exponentially distributed, the number of MRC threats generated in any given period of time is a Poisson random variable (Ross, 1993: 214). The Poisson distribution is frequently used to model the number of events to occur in a period of time (Mendenhall, 1990: 117) and so appears to be a reasonable distribution to model the number of threats to develop over the planning horizon of the simulation.

The exponential distribution is defined by one parameter: the mean time between arrivals. For MRC threats, the mean time between arrivals is expressed in years and defined by the user through the SLAM II control statements.

WW and CW threats are considered to be rare. The model is designed to generate at most one WW threat and one CW threat during the simulation. The time at which a WW or CW threat is generated is determined by two user-defined parameters: the earliest time at which the threat can be generated (min) and the probability (p) that the threat is generated within the planning horizon of the simulation. The generation time is then uniformly distributed with lower limit "min" and upper limit "max" defined by the following equation:

$$\max = \min + \frac{\text{horizon} - \min}{p} \tag{1}$$

where "horizon" is the planning horizon of the simulation. The formulation of this equation is best understood by referring to Figure 3-3.

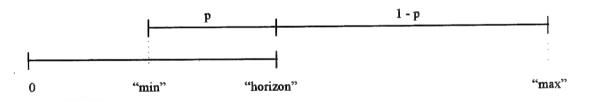

Figure 3-3. Formulating The Distribution of WW and CW Generation.

The probability that a WW or CW threat is generated between the earliest time possible and the end of the simulation is given by

$$p = \frac{\text{horizon} - \min}{\text{max} - \min}$$
 (2)

Solving for "max" yields the above equation. Note that the threat is a factor in the simulation only if the number drawn from the distribution is less than the planning horizon of the simulation.

Occasionally, the state of the simulation "world" affects the generation of threats. The states of the "world" which impact the generation of threats (and the impact they have) are enumerated in Table 3-2 below.

Table 3-2
States of the "World" Which Impact Threat Generation

State of the "World"	Impact on Threat Generation	Rationale
EWI of WW received or WW in progress.	No MRC threats generated.	Any MRC would become part of WW.
on war programme	No CW threats generated.	CW and WW are mutually exclusive.
WW ends.	CW may develop from WW.	World War II experience. The probability of occurrence is user-defined
CW in progress.	MRC generation rates changed.	To reflect DM judgement about stabilizing effect of Cold War. The change is user-defined.
CW ends.	MRC generation rates returned to initial values.	Any stabilizing effect of Cold War ended.

Assignment of Attributes. Once a threat had been generated, it is given attributes which define important characteristics about the threat and which control the flow of the threat through the simulation. Table 3-3 enumerates these threat attributes. An explanation of how attributes are assigned follows the table.

Table 3-3
Threat Attributes

Attribute	Threat(s) Receiving Attribute
Threat Level	All
Estimate of Threat Level	All
Value of Interest	All
Attrition Rate	MRC, WW
Time from EWI to Start of Military Action	All
Projected Duration of Action	All
Deterrent Force Requirement	CW
Projected Deterrent Force Requirement	CW

- Threat Level: The Threat Level is assigned according to a uniform distribution with parameters "min" and "max." The units of measure for Threat Level are MRC-equivalents. The user may define different parameters for all five threat types.
- Estimate of Threat Level: The Estimate of Threat Level is a function of the Threat Level and the accuracy of intelligence estimates. If, for example, intelligence estimates range from 10% below the Threat Level to 15% above the Threat Level, then the Estimate of Threat Level is uniformly distributed with parameters 0.9*TL and 1.15*TL, where TL = Threat Level. The accuracy of intelligence estimates is user-defined and the user may specify a different accuracy for each threat type.
- Value of Interest: The Value of Interest at stake for WW and CW threats is given as 10. For MRC threats, the Value of Interest is assigned according to a discrete distribution defined by the user in the control statements. The user first chooses three values between 0 and 10. These three values are the possible Values of Interest for MRC threats. Then the user defines the probability that threat type 1 has a Value of Interest equal to each of the three chosen values. The user does the same for threat types 2 and 3.
- Attrition Rate: The user may define a distinct Attrition Rate for MRC and WW threat types. If the threat is probabilistically determined to require non-combat action, the Attrition Rate is zero.
- Time from EWI to Start of Military Action: The Time from EWI to Start of Military Action is sampled from a triangular distribution with user-defined parameters "min," mode," and "max." Pritsker points out that "the triangular distribution is used when a most likely value can be ascertained along with

minimum and maximum values...(Pritsker, 1986: 697)" The distribution appeared reasonable for assigning this time component.

- Projected Duration of Action: The Projected Duration of Action is also sampled
 from a triangular distribution with user-defined parameters. This attribute defines
 the length of time required to successfully complete the Military Action if the force
 assigned to the action is equal to the Threat Level. This value will be different
 from the actual duration if the level of forces assigned to the action drops below
 the Threat Level.
- Deterrent Force Requirement: The Deterrent Force Requirement is given to CW threats and defines the amount of force to actually assign to military action. The requirement is simply a user-defined percentage of the Threat Level.
- Projected Deterrent Force Requirement: The Projected Deterrent Force
 Requirement is similar to the Deterrent Force Requirement but is based on the
 Estimate of Threat Level rather than the Threat Level. This projected requirement
 is used in determining force requirements before the CW actually begins.

<u>Determination of Force Requirements</u>. Based on intelligence estimates of the number of forces required to protect its interests against a new threat, the U.S. adjusts its force requirement. The force requirement is dependent on all threats for which the U.S. is either preparing or against which the U.S. is actively engaged. The following table shows which formulas are used to determine the force requirement. The formulas are presented after the table.

Table 3-4

Force Requirement Determination

	Threats Already Present		
Threat Generated	MRC Only	WW	CW
MRC	Formula 1	Not Possible	Formula 3
WW	Formula 2	Not Possible	Formula 2
CW	Formula 3	Not Possible	Not Possible

The force requirement formulas use the following notation:

$$BL = \frac{BuildupLevel(\%)}{100}$$

TL(threat type) = Threat Level of the named threat type

DF = Amount of Deterrent Force Required During Cold War

Formula 1:

$$BL * \sum TL(MRC)$$
 (3)

- Example: U.S. forces are already committed to a 1-MRC threat. The Buildup Level is 150%. EWI of a 1-MRC threat are received. The resultant force requirement is 3 MRC-equivalents. This provides a "safety margin" of 50%, or 1-MRC-equivalent.
- Formula 2:

$$BL*max{TL(WW), \sum TL(MRC)}$$
(4)

- Example: A CW is in progress and the U.S. is preparing for a 1-MRC threat. The Buildup Level is 100%. EWI of a 5-MRC-equivalent WW threat are received. The CW will be "replaced" by the WW and the 1-MRC threat will be absorbed into the WW. The resultant force requirement is 5 MRC-equivalents.
- Formula 3:

$$BL * max \{TL(CW), \sum TL(MRC) + DF\}$$
 (5)

- Example 1: U.S. forces are already committed to a 1-MRC threat. The Buildup Level is 100%. EWI of a 3-MRC-equivalent CW are received, but only 33% (or DF = 1-MRC-equivalent) will be required for military action. The resultant force requirement is max{3, 1 + 1} = 3 MRC-equivalents.
- Example 2: If a 2-MRC threat is added to Example 1, the resultant force requirement is max{3, 3 + 1} = 4 MRC-equivalents.

Note: When using the formulas, the actual Threat Level is used for threats against which military action has already begun, while the Estimate of Threat Level is used for threats for which EWI have just been received.

<u>Time Between EWI and Military Action</u>. This is the time between the EWI of a threat and the beginning of military action. If the current force level is below the force requirement, force buildup begins. If force buildup is necessary, this "preparation" time may or may not be sufficient to raise the Total Force level up to the Force Requirement.

Military Action. At the end of the preparation time, the military action begins. The actual threat level becomes known and the force requirement is recalculated as described above. If the Force Requirement exceeds Total Force, then force buildup begins or continues. Table 3-5 lists the additional events which take place at this time.

Table 3-5

Rules for Beginning Military Action

Threat Entering Action	Event	
MRC	Available forces are assigned to action. Attrition begins if action is warfare.	
ww .	Any previous MRCs end. If the sum of those MRCs is greater than the size of the WW, then the size of the WW is adjusted to equal the sum of the MRCs. Available forces are assigned to action. Attrition begins.	
CW	Available forces are assigned to deterrence. If forces insufficient and there are any MRCs in action, the CW "preempts" forces from the MRCs.	

Involvement in the interest continues until the U.S. attains its objective or has too few forces to continue its pursuit. If force assigned drops below the Threat Level, the duration of the operation will be lengthened, unless the forces drop below the Lose Threshold, in which case the U.S. withdraws and loses the interest at stake.

End of Event. At this point the military action ends (successfully or unsuccessfully) and force requirements are recalculated (as described above) to reflect the end of a threat. If current force levels exceed force requirements, force demobilization begin.

Attrition, Buildup, and Demobilization.

The simulation model has three "subroutines" which handle the attrition, buildup, and demobilization of forces. The subroutines work by simply advancing the simulation clock a short time interval and then either increasing or decreasing the Total Force Level. The user defines the attrition, buildup, and demobilization rates in the control statements.

Attrition. When determining the amount of attrition during a military action, it is assumed that, since attrition is inflicted by the enemy, the attrition *rate* is applied to the Threat Level rather than to the actual amount of forces committed to the military action in question. For example, assume that the Threat Level is 2 MRC-equivalents, the amount of forces committed to the military action is 1.75 MRC-equivalents, the attrition rate is 10% per year, and the "clock" is advanced 0.04 year. Then the amount of attrition over the time interval is

$$2(MRC) * \frac{10\%}{Year} * 0.04(Year) = 0.008(MRC)$$
(6)

The amount of force committed to the military action is, thus, reduced from 1.75 MRC-equivalents to 1.742 MRC-equivalents over the period of 0.04 year (or approximately 2 weeks). In turn, the Total Force Level is decreased by 0.008 MRC-equivalents.

NOTE: There are other, more sophisticated methods of modeling attrition than that presented here. Substitution of such models in the simulation may be appropriate.

Buildup and Demobilization. The buildup and demobilization of forces works in fashion similar to attrition, but the rates are given in MRC-equivalents per year. Thus, if the Buildup Rate is 0.5 MRC-equivalents per year, then over a two week interval the Total Force Level is increased by 0.002 MRC-equivalents.

Costs.

There are three costs used to track the billions of dollars required to maintain, buildup, and demobilize forces. Each time there's a change in the amount of Total Force, a "maintenance" cost is assessed. If Total Force level "A" began at time 1, for example, and the Total Force changes to level "B" at time 2, then the "maintenance" cost is the cost of maintaining level "A" from time 1 to time 2. The "maintenance" cost for that time period is calculated by multiplying the Total Force Cost Per Year for level "A" by the length of the time period. Then a new Total Force Cost Per Year is determined as follows:

- Before the simulation is started, the user specifies five Total Force levels and their respective costs per year. These five Total Force levels form six intervals.
- The new Total Force level is compared to the user-specified Total Force levels to determine in which interval it falls.
- Through linear interpolation (or extrapolation) the cost of the new Total Force level is determined.
- For example, suppose that the five Total Force levels specified are 0.5, 1, 2, 3, and 4 MRC-equivalents with respective costs, 100, 185, 250, 300, and 325 billion dollars. If the new Total Force level is 2.5 MRC-equivalents, then this new force level falls in the interval (2, 3) and by linear interpolation has a cost of \$275 billion per year.

Buildup and demobilization costs are determined by assessing penalties to the change in Total Force Cost Per Year. During any buildup or demobilization of forces, the change

in the Total Force Cost Per Year is multiplied by the time interval and the penalty. For example, if the previous and current Total Force Costs Per Year are \$275 billion and \$276 billion, respectively, the time interval is 0.04 year, and the Buildup Penalty 20%, then the additional cost of building force over this two-week interval is

$$(\$276 - \$275) * 0.04$$
Year $* 20\% = \$0.008$ (7)

or \$8 million.

Risks.

There are a number of risks important to the choice of policy alternatives. The first risk is the risk of losing valuable U.S. interests. Recall that every U.S. interest has a value defined on a 0 to 10 utility scale. When a military action is lost, so is the value of the interest at stake. Thus, the risk of losing interests is determined by the sum of the values of all the interests lost during the simulation.

The second risk could be thought of as a Duration Penalty. That is, if the amount of forces assigned to a military action is below the Threat Level, then the Duration of Military Action is increased, or penalized. The increase is determined by the shortage in forces, the amount that the "clock" advances, and the Duration Penalty parameter (defined by the user in the control statements). For example, if the Threat Level is 1 MRC-equivalent and the amount of forces assigned to the threat is 0.9 MRC-equivalents, then the shortage is 10%. The shortage is multiplied by the Duration Penalty and the "clock" time interval. So, if the Duration Penalty is 200%, then the Duration of the Military Action will be increased by

or approximately 3 days. In words, if there is a 10% shortage in required forces over a two-week period, the duration of the military action will be increased 3 days. The significance of this penalty is that there will be additional forces lost to attrition beyond what there would have been if sufficient forces were available.

The third risk is the probability that Total Force falls below the Force Requirement.

Since the Force Requirement may have a "safety margin" built into it, a risk of even greater importance is the probability that Total Force falls below the amount of force actually required for military action. Both of these risks are reported by the simulation.

The Program Code.

Appendix A includes the program code for the model with a description of how to input parameters and build the control statements.

Parameter Selection.

All the user-defined parameters for the simulation are enumerated in Appendix A.

With a few exceptions, the parameters reflect personal judgements formed after a cursory review of post-World War II history, with particular attention to recent events. The few exceptions are explained below.

<u>Buildup Rate</u>. The Buildup Rate is actually one of the decision variables rather than a static parameter. It seemed important to set an upper bound on the Buildup Rate for the analysis. Table 3-6 summarizes the number of "units" required for one MRC. Lewis claims that, on the average, 6.5 aircraft must be produced each year to sustain a TFW

(Lewis, 1989: 44). A 2 MRC-equivalent military includes 20 TFW-equivalents. At a rate of 6.5 aircraft per TFW per year, industry must produce 130 aircraft a year to sustain a 2 MRC-equivalent Air Force. If an additional 10 TFWs were to be built in a year (a Buildup Rate of 1 MRC per year), a total of 850 aircraft would need to be built, or approximately 6.5 times the normal rate. This seemed like an attainable Buildup Rate, keeping in mind that the Buildup Cost Penalty should reflect the Buildup Rate. (Unfortunately, data was not available to make a similar claim about Army or Navy units.)

Table 3-6
Composition of One MRC

Military Service	Units	Individual Components
Army	5 Divisions	75,000 Soldiers
Navy	5 Carriers Battle Groups	5 Carriers + Support Ships
Air Force	10 Tactical Fighter Wings	720 Aircraft

Total Force Costs. Considerable historical data on defense expenditures is available (OMB, 1994; Air Force Association, 1994: 37); however, it does not lend itself very easily to an *unarguable* projection of future force costs. Figure 3-4 shows a plot of historical cost data and an approximation of those costs. Data dating back to the mid-1980's was normalized into constant 1995 dollars and, for each year, the force size was converted into MRC-equivalents. The approximating line shown in the figure is defined by the formula

$$Cost(\$billions) = 132 * \sqrt{2 * MRC}$$
 (9)

The term under the radical was chosen to provide a concave curve which begins at the origin (assuming that \$0 give no capability), rises quickly at first (to reflect the front-end costs of infrastructure), and then increases at a decreasing rate to reflect a decreasing

marginal cost of additional forces. The constant term was chosen to scale the curve upward to "fit" through the historical data.

The five Total Force Levels entered into the control statements were 0.5, 1, 2, 3, and 4, and approximate costs for these levels were determined using the above equation.

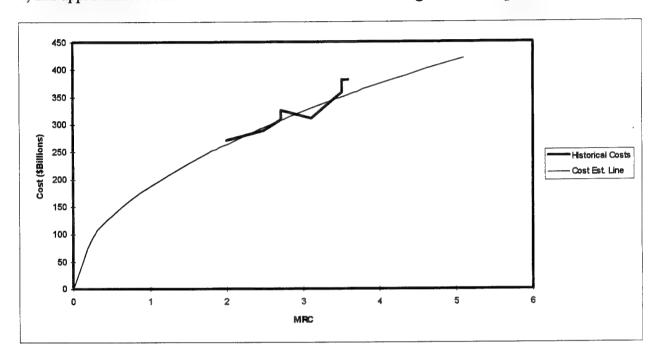

Figure 3-4. Approximating Force Costs

Design of Experiment.

Table 3-7 enumerates the policy alternatives evaluated by the methodology. The levels for each decision variable were chosen as follows:

- Three Base Force levels were chosen. A 3-MRC Base Force (similar in size to Cold War force levels) was evaluated to provide a baseline by which to compare other alternatives. A 2-MRC Base Force was evaluated because it is the current Base Force "of choice." A 1-MRC Base Force was evaluated to investigate the possibility of reducing the Base Force even further.
- Two Buildup Levels were evaluated: 100% of the Force Requirement and 150% of the Force Requirement. These two levels permit comparison of policy alternatives with no "safety margin" and with a 50% "safety margin," respectively.

- Two Buildup Rates were evaluated: 0.2 and 1 MRC per year. A Buildup Rate of 0.2 MRC per year is a relatively low Buildup Rate, while a 1 MRC per year rate is relatively high (as explained earlier).
- Two Demobilization Rates were evaluated: 0.2 and 1 MRC per year. These rates are chosen to compare a relatively low rate with a relatively high rate.

With the given levels of each decision variable, a total of 24 policy alternatives were evaluated. Each alternative was simulated 100 times. In general, more simulation runs means better statistical data. The choice of simulating 100 times per alternative was made primarily according to limitations in processing time.

Table 3-7
Design of Experiment

Alternative	Base Force (MRC)	Buildup Level (%)	Buildup Rate (MRC/Year)	Demobilization Rate (MRC/Year)
1	1	100	1	1
2	1	100	1	0.2
3	1	100	0.2	1
4	1	100	0.2	0.2
5	1	150	1	1
6	1	150	1	0.2
7	1	150	0.2	1
8	1	150	0.2	0.2
9	2	100	1	1
10	2	100	1	0.2
11	2	100	0.2	1
12	2	100	0.2	0.2
13	2	150	1	1
14	2	150	1	0.2
15	2	150	0.2	1
16	2	150	0.2	0.2
17	3	100	1	1
18	3	100	1	0.2
19	3	100	0.2	1
20	3	100	0.2	0.2
21	3	150	11	1
22	3	150	1	0.2
23	3	150	0.2	1
24	3	150	0.2	0.2

IV. Findings

This chapter is divided into three sections. The first section offers an example of a simulation timeline. The second section presents a characterization of the costs and risks associated with each alternative. The third section presents plots useful in evaluating alternatives against the costs and risks.

Example of a Simulation Timeline.

The three plots which follow demonstrate how certain key variables respond over time to simulated events. The plots are from one distinct simulation run of policy Alternative 9 (2-MRC Base Force, 100% Buildup Level, 1 MRC-per-year Buildup Rate, and 1 MRC-per-year Demobilization Rate).

The first plot (Figure 4-1) shows how Total Force and the Force Requirement change over time. Table 4-1 explains the most meaningful "events" in the timeline.

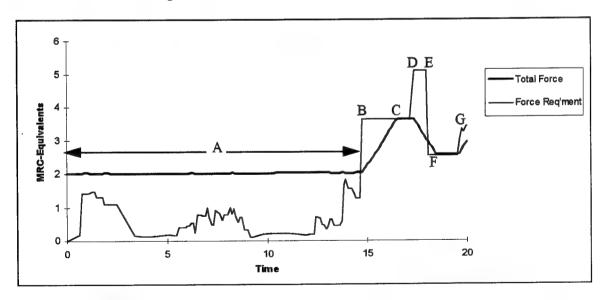

Figure 4-1. Timeline Example (Total Force vs. Force Requirement)

Table 4-1

Key Events in Figure 4-1

Time	"Event"		
Α	A period of time when various MRC-type threats are generated and acted upon.		
В	EWI of a World War are received. The Force Requirement is adjusted upward according to intelligence estimates of the Threat Level of the impending war. Buildup of force begins.		
С	The Total Force has reached the Force Requirement and the buildup ends. Recall that with a Buildup Level of 100%, there is no "safety margin."		
D	The World War begins and the Force Requirement is adjusted upward to reflect the actual Threat Level. Attrition begins.		
Е	Force buildup is not able to "keep up" with attrition. Total Force drops below the Lose Threshold and the World War ends unfavorably for the U.S.		
F	A Cold War period evolves out of the World War. Forces are demobilized to the new Force Requirement.		
G	MRC-type threats begin to developed again.		

Figure 4-2 shows two variables: 1) Total Force and 2) Total Force less the Force Requirement. Table 4-2 summarizes the key events in this plot.

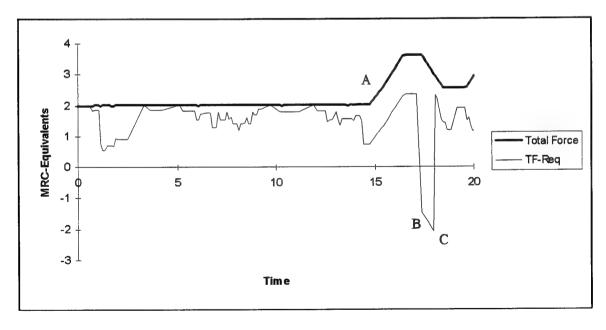

Figure 4-2. Timeline Example (Total Force vs. Total Force less Force Requirement)

Table 4-2

Key Events in Figure 4-2

Time	"Event"
Α	Force buildup begins in response to EWI of World War.
В	The World War begins and the difference between Total Force and the Force Requirement drops below zero. In other words, the Force Requirement exceeds Total Force.
С	After a period of attrition, Total Force drops to a level where the Force Requirement exceeds Total Force by the Lose Threshold. The World War ends unfavorably for the U.S.

Figure 4-3 shows Total Force versus the Cost per Year. Point "A" marks the time when military buildup begins.

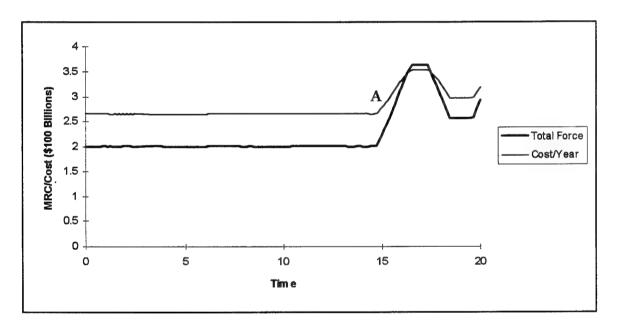

Figure 4-3. Timeline Example (Total Force vs. Cost/Year)

Characterization of Costs and Risks.

Appendix B contains a complete listing of the simulation output for all 24 alternatives. The discussion which follows summarizes this data. Recall that 100 simulation runs were made for each alternative. In the plots below, the mean of these 100 runs is used as the single-point estimator of the "true" value of the variables presented.

<u>Total Cost</u>. Figure 4-4 shows the Total Cost for each policy alternative. When a line is added to connect the points, the following patterns emerge:

- There is a general trend upward from left to right. This trend is explained by the fact that the alternatives to the left have a Base Force of 1 while those to the right have a Base Force of 3.
- There are regular peaks and dips. The peaks are alternatives with the higher Buildup Rate while the dips are the alternatives with the lower Buildup Rate. Obviously, the greater penalty associated with the higher Buildup Rate increases overall cost.
- Within each peak and dip are two alternatives. Both alternatives in any given peak
 or dip are identical except for the Demobilization Rate. The first alternative in
 each peak has the higher Demobilization Rate and generally has a slightly lower
 Total Cost. Since the higher Demobilization Rate was not penalized more than the
 lower rate, it would make sense to demobilize quickly and return more quickly to a
 lower maintenance cost.
- There is a greater difference between the peaks and dips to the left than between the peaks and dips to the right. This might suggest (and reasonably so) that, with a larger Base Force, there is less reliance on buildup and demobilization.

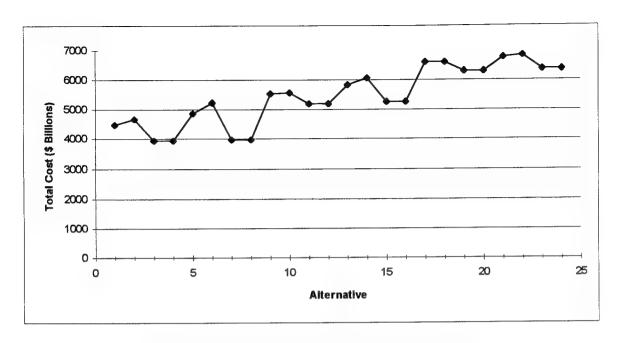

Figure 4-4. The Total Cost of Each Alternative

Figure 4-5 shows the mean and range of Total Costs for each alternative. Note that:

- The range of Total Costs appears to be wider for alternatives with a 150% Buildup Level (Alternatives 5 to 8, 13 to 16, 21 to 24) than for similar alternatives with a 100% Buildup Level (Alternatives 1 to 4, 9 to 12, 17 to 20, respectively).
- The range of Total Costs appears shorter for alternatives with a higher Base Force.

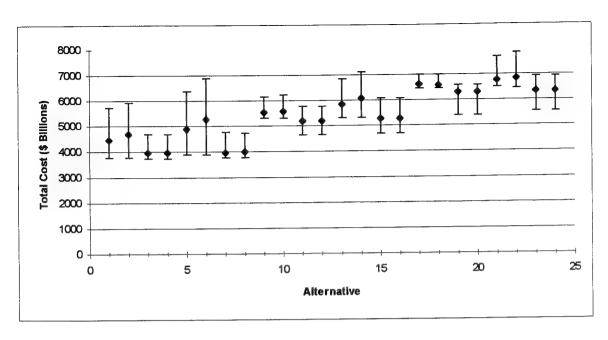

Figure 4-5. Variability in Total Cost

Value of Interest Lost. Figure 4-6 shows the mean Value of Interest Lost for each alternative, while Figure 4-7 shows the complete range of values for each alternative.

Note that:

- There is a downward trend in the mean values from left to right. This suggests that there is less risk of losing U.S. interests when a higher Base Force is maintained.
- The dips include alternatives with the higher Buildup Rate, suggesting that there is less risk of losing U.S. interests when forces are built up quickly.
- In general, the second alternative in each pair (i.e., peak or dip) has a lower Value of Interest Lost. This suggests that a low Demobilization Rate helps reduce the Value of Interest Lost.

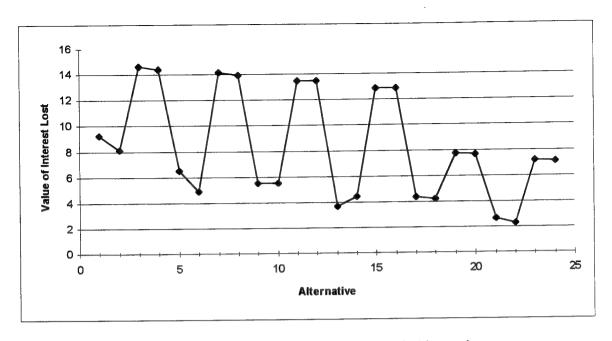

Figure 4-6. Value of Interest Lost for Each Alternative

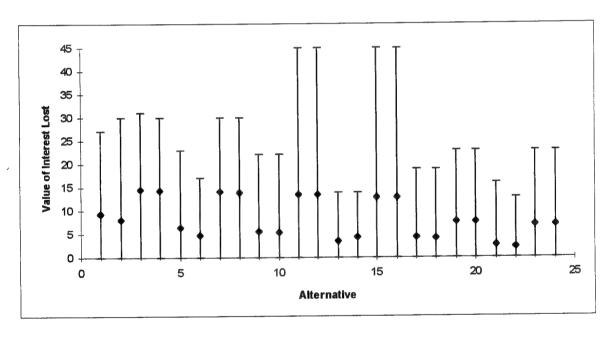

Figure 4-7. Variability in Value of Interest Lost

Percent of Time the Force Requirement Exceeds Total Force. Figures 4-8 and 4-9

summarize the data on the percent of time that the Force Requirement exceeds Total

Force. Note that:

- Higher Base Forces and the higher Buildup Rate tend to reduce the risk that the Force Requirement will exceed the Total Force.
- The risk of being unprepared is as great for Alternatives 12, 13, 16, and 17 (where the Base Force is 2 MRC-equivalents) as it is for Alternatives 3, 4, 7, and 8 (where the Base Force is 1 MRC-equivalent). This suggests that having a higher Buildup Rate may be more important, in some scenarios, than having a larger Base Force.

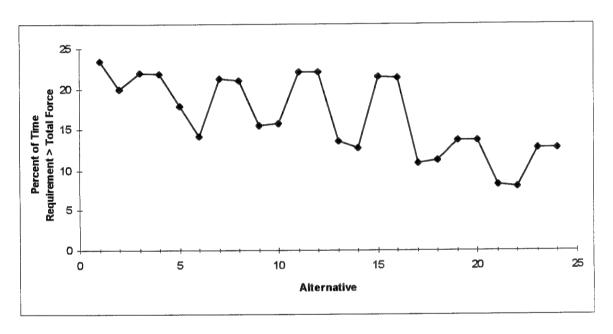

Figure 4-8. Percent of Time Requirement Exceeds Total Force for Each Alternative

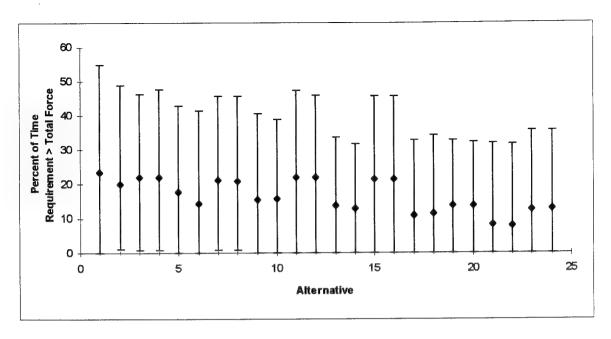

Figure 4-9. Variability in Percent of Time Requirement Exceeds Total Force

Evaluating Alternatives Against the Costs and Risks.

The following plots present several "views" of the policy alternatives. In each "view," the alternatives are plotted according to a pair of costs and/or risks. With each "view," insights can be gained and certain alternatives can be eliminated as too costly or too risky.

The plot in Figure 4-10 has Value of Interest Lost on the x-axis and Total Cost on the y-axis. When each alternative is placed on the plot according its mean Value of Interest Lost and its mean Total Cost, certain groupings of alternatives become apparent. In fact, in all of the "views" of the policy alternatives, these same groupings will remain relatively congruous. The groupings are tabulated in Table 4-3.

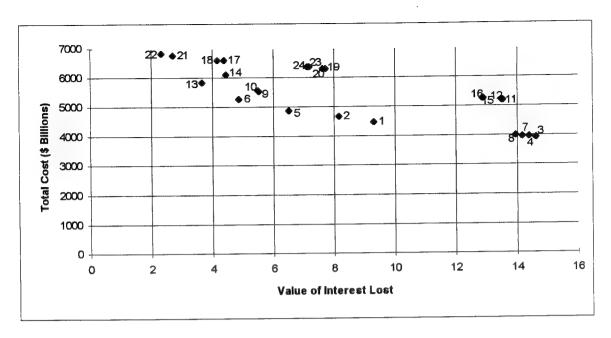

Figure 4-10. Total Cost vs. Value of Interest Lost

Table 4-3
Groupings of Alternatives

Grouping	Alternatives	Differentiating Characteristics	
Group I	3, 4, 7, 8	Base Force = 1, Buildup Rate = 0.2	
Group II	11, 12, 15, 16	Base Force = 2, Buildup Rate = 0.2	
Group III	19, 20, 23, 24	Base Force = 3, Buildup Rate = 0.2	
Pair (1, 2)	1, 2	Base Force = 1, Buildup Level = 100%, Buildup Rate = 1	
Pair (5, 6)	5, 6	Base Force = 1, Buildup Level = 150%, Buildup Rate = 1	
Pair (9, 10)	9, 10	Base Force = 2, Buildup Level = 100%, Buildup Rate = 1	
Pair (13, 14)	13, 14	Base Force = 2, Buildup Level = 150%, Buildup Rate = 1	
Pair (17, 18)	17, 18	Base Force = 3, Buildup Level = 100%, Buildup Rate = 1	
Pair (21, 22)	21, 22	Base Force = 3, Buildup Level = 150%, Buildup Rate = 1	

Figure 4-10 is now repeated with the alternative Groups circled and alternative Pairs connected by a line.

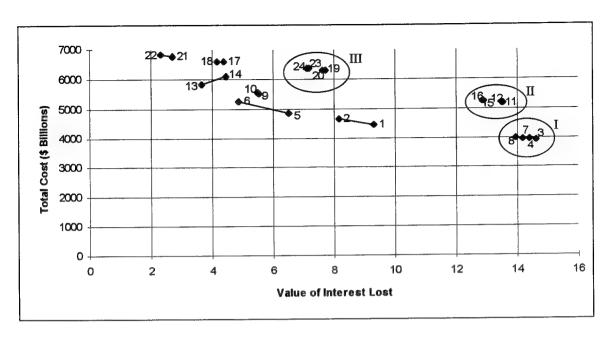

Figure 4-11. Total Cost vs. Value of Interest Lost (with Alternatives Grouped)

With the groundwork laid, attention can now be turned to evaluating alternatives.

Suggesting that being to the lower left corner of the plot is best, the following observations can be made:

- Since World War carries a Value of Interest equal to 10, choosing an alternative with a Value of Interest Lost less than 10 suggests that on the average no World Wars are lost. Eliminating alternatives with a Value of Interest Lost greater than or equal to 10 eliminates Groups I and II. These two groups consist of the alternatives with 1- or 2-MRC Base Forces and the lower Buildup Rate.
- Group III is dominated by six other alternatives: 5, 6, 9, 10, 13, and 14.
- Only Alternatives with the higher Buildup Rate seem to be reasonable choices.
 Among those, Alternatives 9, 10, 14, 17, and 18 are also dominated by other alternatives.
- Alternatives 1, 2, 5, 6, 13, 21, 22 are left undominated.

The next metric used to evaluate alternatives is the percent of time that the Force Requirement exceeds Total Force. Plotting this metric versus Total Cost and Value of Interest Lost yields Figures 4-12 and 4-13, respectively. The following observations can be made from these figures:

- Even with the higher Buildup Rate, the Force Requirement will exceed Total Force anywhere from 5 to 25 percent of the time.
- It might be useful to identify a maximum acceptable risk of having the Force Requirement exceed Total Force. If, for example, the maximum acceptable risk is 20%, then Groups I and II can be eliminated, as well as Alternative Pair (1, 2).
- In Figure 4-12, only Groups II and III and Alternatives 1, 9, and 10 are dominated.
- In Figure 4-13, Alternative 22 dominates all others.

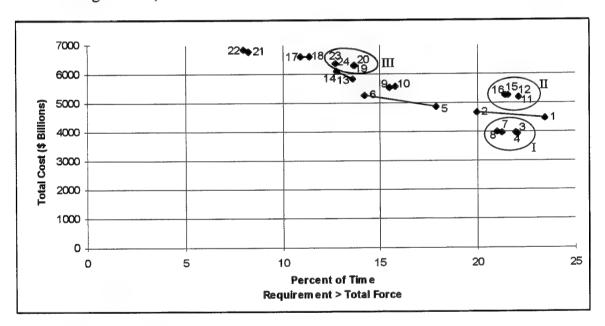

Figure 4-12. Total Cost vs. Percent of Time Force Requirement Exceeds Total Force

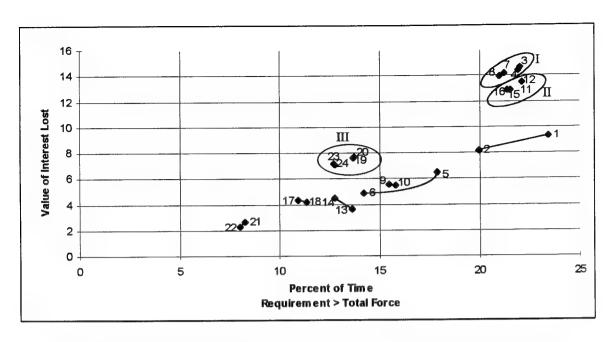

Figure 4-13. Value of Interest Lost vs. Percent of Time Force Requirement Exceeds Total Force

V. Conclusions and Recommendations

Conclusions.

Alternative 22 is the only alternative which is undominated in all "views."

- Alternative 22 consists of a 3-MRC Base Force, a 150% Buildup Level, a 1 MRC-per-year Buildup Rate, and a 0.2 MRC-per-year Demobilization Rate.
- Alternative 22 closely resembles the U.S. policy followed during the later years of the Cold War.
- Alternative 22 results in the lowest Value of Interest Lost and the lowest percent of time that the Force Requirement exceeds Total Force.
- However, Alternative 22 has the highest Total Cost of all alternatives. This high cost is the reason that such a policy alternative is being abandoned in the post-Cold War period.

Buildup Rate appears to be a key factor.

- A high Buildup Rate helps compensate for a smaller Base Force.
- The best policy should probably include the highest Buildup Rate possible. Unfortunately, the rate at which forces can be built up depends on the health of the defense-industrial base. The defense-industrial base is being weakened over time and is probably dependent, in part, on the size of the Base Force (i.e., the higher the Base Force, the more production that is required to maintain the Base Force).

The optimal policy alternative might be identified by determining the maximum amount of acceptable risk and choosing an alternative with acceptable risk and the lowest cost.

Recommendation.

Further study might include:

• Investigate how the timing of EWI influences the choice of alternatives. The timing of EWI is, in part, a function of the ability of the intelligence community to gather and process these EWI, but is also a function of how National Command

Authorities choose to respond to the EWI received. Such an investigation can be made with the current model by modifying EWI-timing parameters.

- Study the work that has been done to model force attrition and "upgrade" the attrition subroutine in the simulation model.
- Make the assumption that the frequency and nature of threats are dependent on the
 force structure and investigate how this assumption influences the choice of
 alternatives. Such an investigation can be made with the current model by
 changing the threat parameters when force structure parameters are changed.
- Model buildup rates as a function of the Base Force.
- Gather better cost data for future experimentation.

Appendix A: Simulation Model

MICROSOFT EXCEL SPREADSHEET

Figure A-1 shows the spreadsheet used to define simulation parameters and build the control statements. In the control statements, the parameters are generally listed in array form. To assure that the proper parameters were placed in the correct position in the arrays, the spreadsheet was linked to a Microsoft Word document. The Word document contained the text required for the control statements and drew the actual numbers from the spreadsheet through the link. The Word document was then saved as a text-only file and was ready for use by SLAM II.

ATTRIBUTES, VARIABLES, AND FILES

Table A-1 gives a complete list of the attributes, variables, and files used in the network model.

Table A-1
Attributes, Variables, and Files

	ATRIBUTES	VARIABLES	FILE
1	Event Type	Total Force (TF)	Buildup Gate
2	Actual Conflict Level	Available Force (AF)	Await WW
	EWI Estimate of Level	*Initial Base Force	Await CW
4	P{Low Interest}	Previous Maint Cost/Year	Preempt CW
5	P{Medium Interest}	Current Maint Cost/Year	Demob Gate
6	P{High Interest}	Time of last change in TF	Await MRC
7	Interest	Cum TF Cost	
8	Priority	*Build/Attrit/Demob Increm	
9	EWI Time	*Buildup Level/Safety Margin (%)	
10	Attrition Rate	*Buildup Rate (TF/Year)	
11	Time from EWI to Event	Buildup Addition	
12	Start Time	*Buildup Cost Penalty (%)	
13	Projected Conflict Duration	Cum Buildup Cost Penalty	
	Force Assigned	Current Buildup Cost/Year	
15	Duration Remaining	Attrition Amount	
16	Projected End Time	*Demob Rate (TF/Year)	
17		Demobilization Amount	
18	Projected DF Req	*Demob Cost Penalty (%)	
19	Actual DF Req	Cum Demob Cost Penalty	
20		TF Req	
21		MRC TF Req	
22	Force Shortage	WW TF Req	
23	Force Shortage %	CW TF Req	
24		Committed Force Req	
25		Interest Lost	
26		Lose Threshhold (Decimal)	
27		Current Demob Cost/Year	
28		Force in MRC/WW	
29		Force in CW	
30		Total Committed Force

<u>Vita</u>

Captain Michael L. Fredley was born on 13 November 1964 in Hammond, Indiana.

He graduated from Mason City High School in Mason City, Iowa, in 1982 and after a

two-year Church mission in Paris, France, attended the University of Utah. He graduated

Cum Laude from the University of Utah in June 1989 with a Bachelor of Science in

Mathematics. Upon graduation, he received a regular commission in the USAF and

served his first tour of duty at the 49th Test Squadron, Barksdale AFB, Louisiana. Upon

joining the 49th, he became lead engineer for the testing and certification of conventional

munitions from the B-52 bomber. Later he became lead engineer for B-1B conventional

follow-on test and evaluation. He continued his testing duties until entering the School of

Engineering, Air Force Institute of Technology, in August 1993.

13. ABSTRACT (Maximum 200 words	13. ABSTRACT (Maximum 200 words) The chiertine of this research was to develop an analytical framework to assess future force structure												
The objective of this research was to develop an analytical framework to assess nuture force structure													
requirements under the major uncertainties inherent in the post-Cold War era. Among the													
uncertainties are the frequency and nature of future threats to U.S. interests and the cost of maintaining, building, and demobilizing forces. The centerpiece of the methodology is a computer													
maintaining building and	damobilizing forces. The	centerniece of the method	ology is a computer										
maintaining, building, and	demodifizing forces. The	II C interests and the ac	tions the IIS takes to										
model which simulates the	e development of threats to	O.S. mieresis and the ac	the lifement maliar										
protect those interests. Fi	rom this simulation, the co	sts and risks associated W	in unierent poncy										
alternatives can be estimat	ted. The simulation is set	within a broader decision-	analysis framework										
which provides the philoso	ophy for determining the in	nputs to the simulation and	l for analyzing the										
output from the simulation	n. The research included a	n analysis of 24 policy alt	ernatives involving the										
size of the Rase Force the	e "safety margin" maintain	ed between the force size	and the force										
magazinament the meta of f	rea builden and the rate	of force demobilization T	he results suggest that										
requirement, the rate of force buildup, and the rate of force demobilization. The results suggest that the buildup rate is a key factor in lowering the costs of the U.S. military while controlling the risk of													
being unable to protect U.S. interests.
